

AGU Press Conference

Spring at the South Pole of Mars

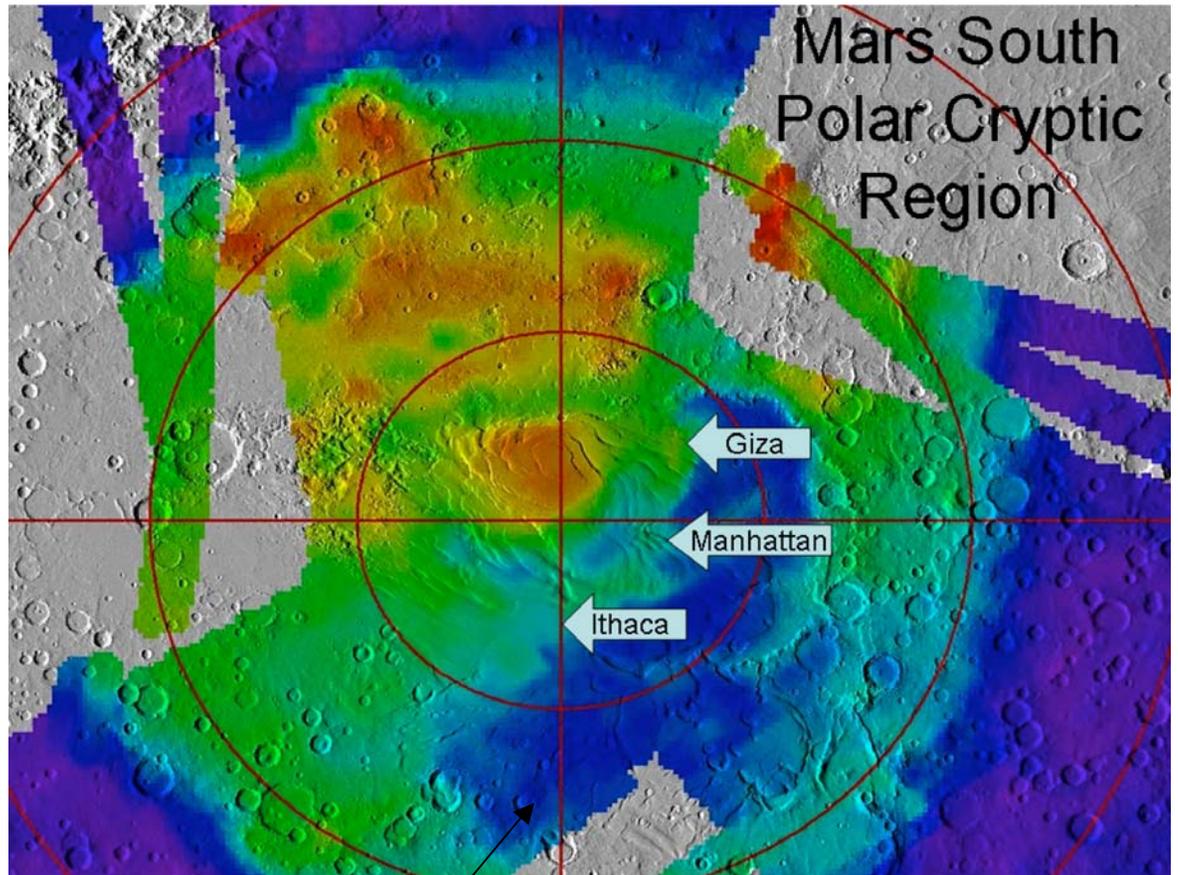

C. J. Hansen, A. McEwen
and the HiRISE Team
December 2007

Setting the Stage...

- Mars, like earth, experiences seasons
- In the winter a **seasonal polar cap of carbon dioxide** (CO₂) ice covers latitudes up to ~55°
- MRO has just completed a campaign to observe the spring sublimation (evaporation) of the CO₂ ice
- Focus has been on 3 sites in the “**cryptic terrain**”, a region that stays cold even as it gradually darkens
- *This region is home to topography unlike anything on planet earth*

Map is courtesy of Mars Global Surveyor Thermal Emission Spectrometer and Mars Orbiter Laser Altimeter

This blue region is the cryptic terrain

Hypothesis: The CO₂ seasonal ice in the cryptic terrain is translucent, allowing sunlight to penetrate through the ice to the surface below. The ice then sublimates from the bottom of the slab, eroding channels in the surface below. (H. Kieffer, 2000)

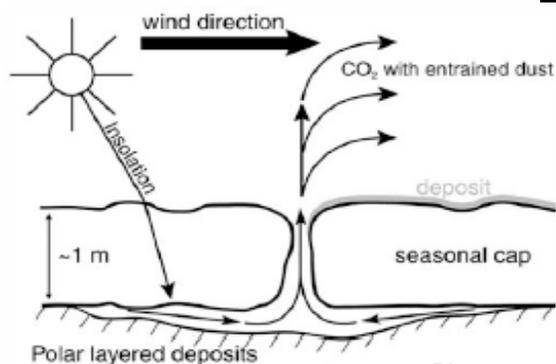

Four Components of Surface, Apparent in Color

- Muted red: dark surface, appearance muted by translucent ice
- Dark fans: dust brought up from surface, laying on top of translucent ice
- Translucent ice: “visible” by effect it has on surface tone
- Bright bluish: gas re-condensed on top of the ice as fine-grained bright frost

False Color

PSP_002942_0935

Piqueux et al., JGR 2003

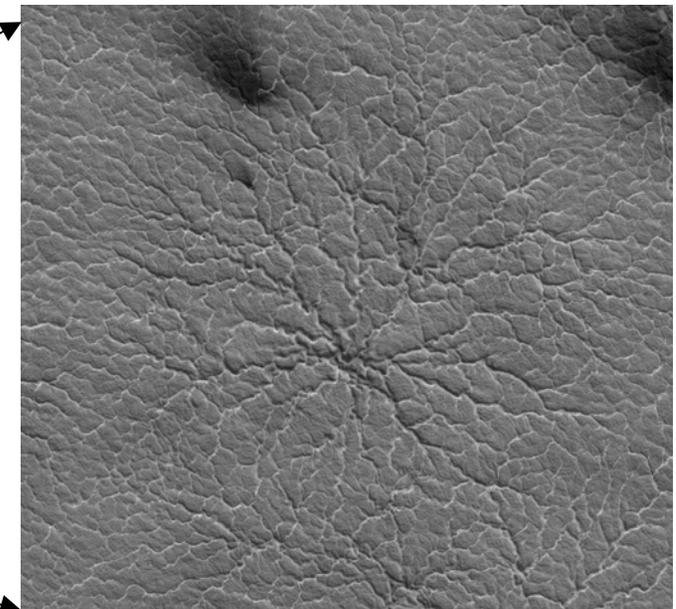

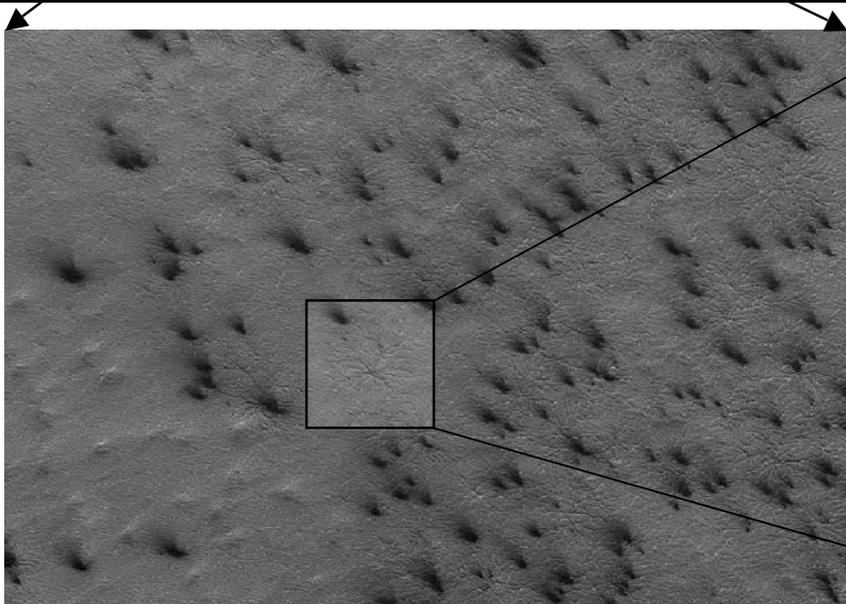

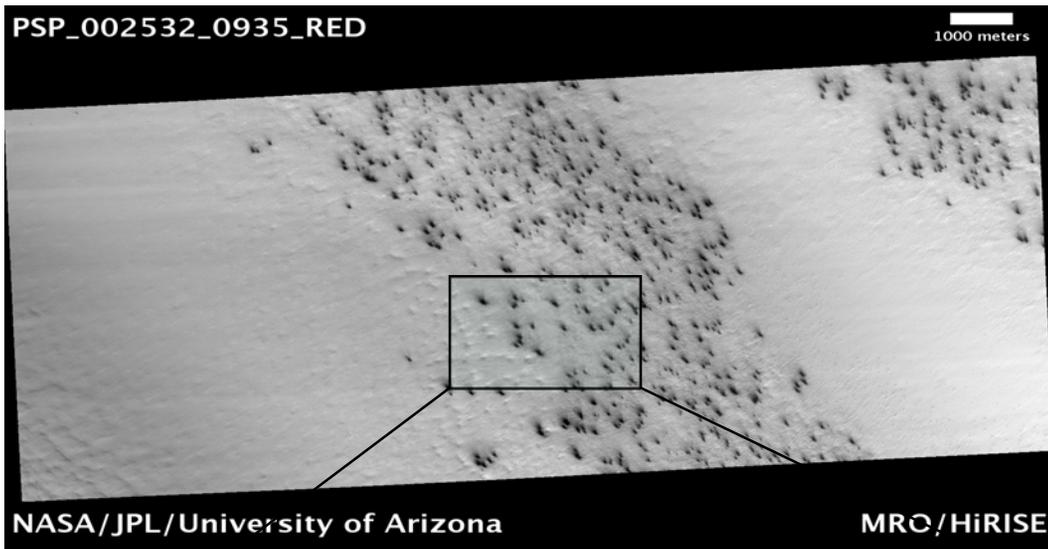

The surface beneath the seasonal ice is water-ice cemented dirt covered by a ~ 5 cm layer of dust (silt-sized particles)

Anatomy of a “Spider”

- Associated with more fans early in the season
- Radially organized channels which deepen and widen as they come to the center
- Spiders often drape over the local topography
- Channels often widen and deepen as *they go uphill*

Consistent with gas as the erosive agent

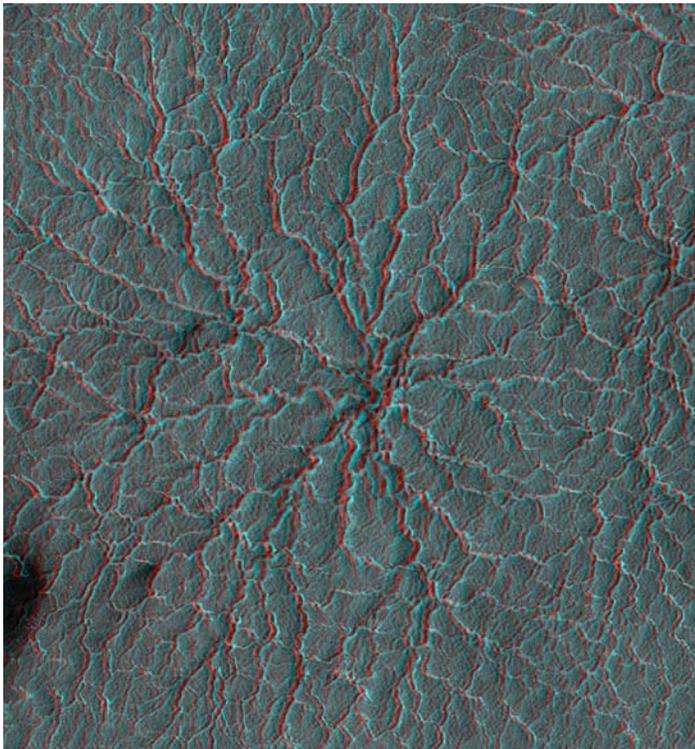

Spider is ~0.55 km in diameter

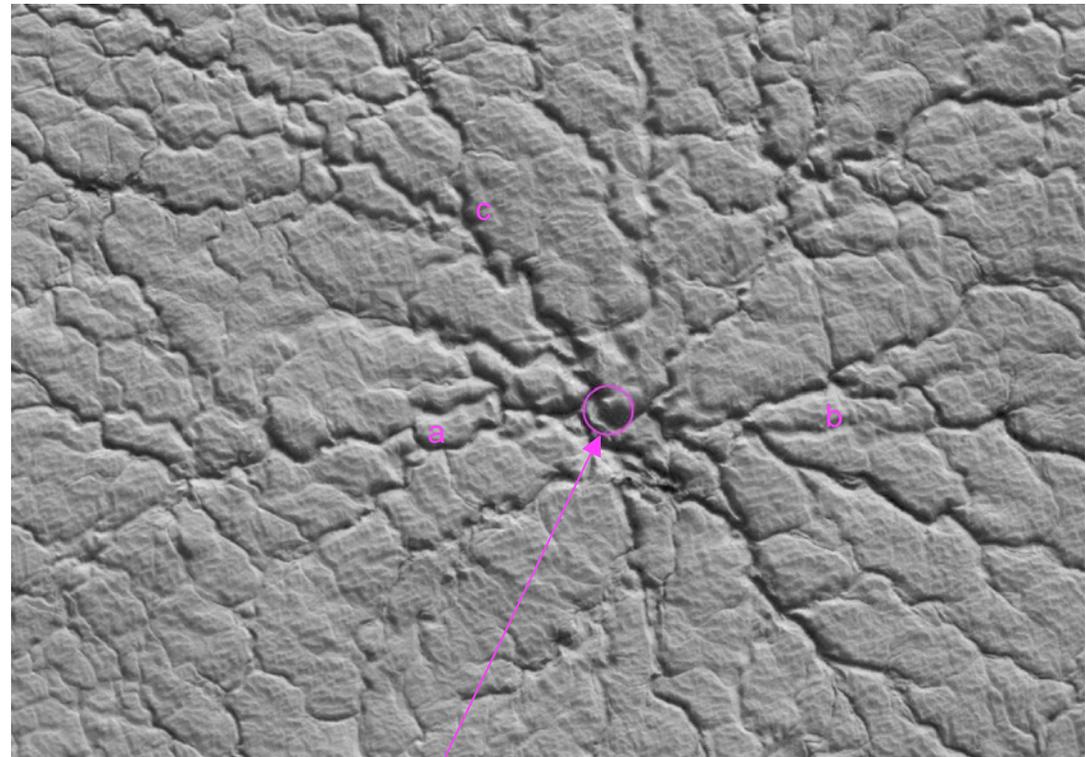

Spider dimensions

- from shadow measurements after seasonal ice was gone
- incidence angle = 74.88°

Overall Spider size:
~550 m diameter

Spider Size

PSP_005579_0935

Center Depth: 1.8 m

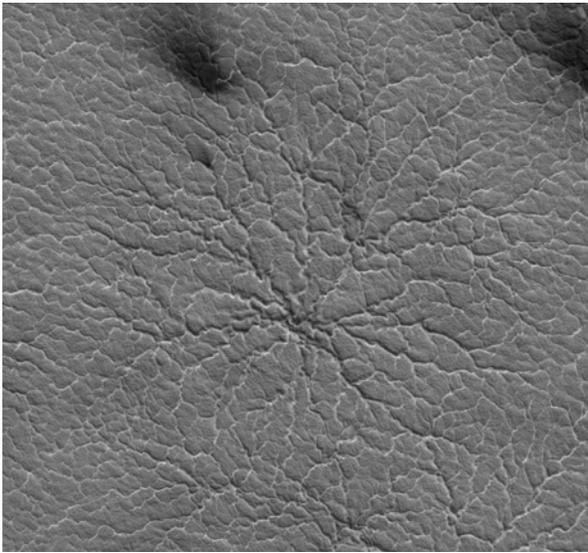

Channel Widths, Depths

- a 5 m wide, 1 m deep
- b 3.4 m wide, 0.7 m deep
- c 5 m wide, 0.6 m deep

Stereo pair from
PSP_002532_0935 and
PSP_002533_0935

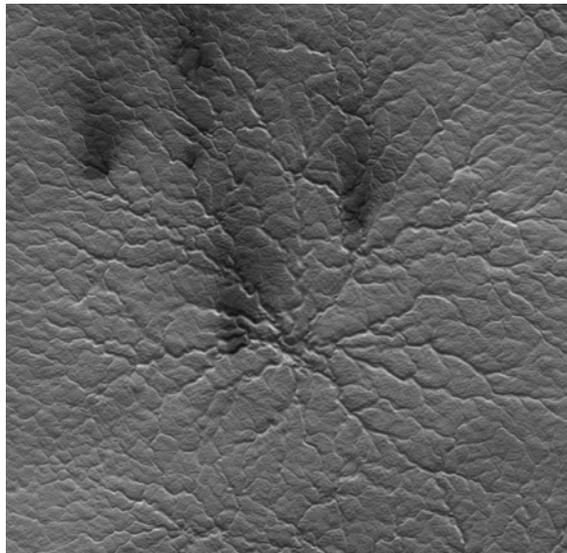

Spider Time Lapse Series

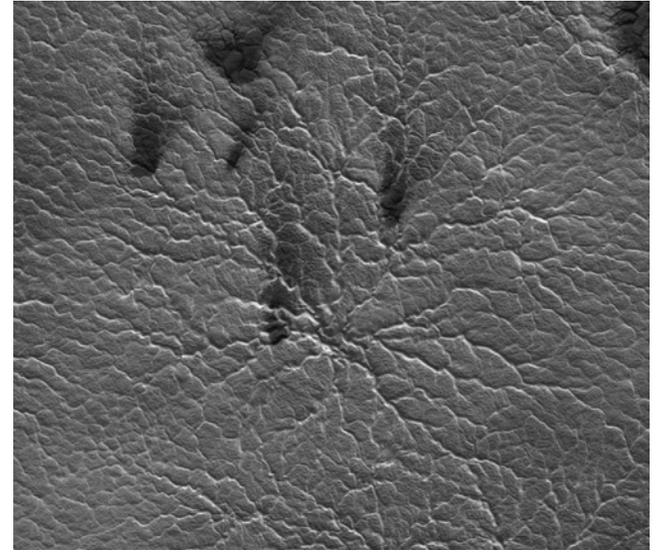

PSP_002532_0935

Ls = 181.1

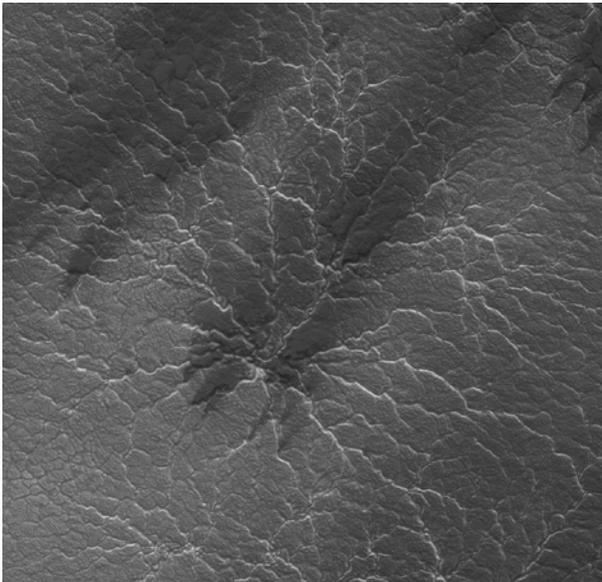

PSP_002850_0935

Ls = 195.4

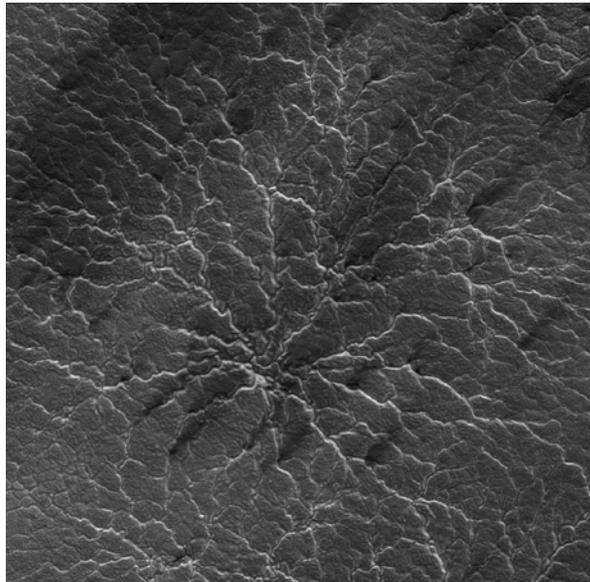

PSP_002942_0935

Ls = 199.6

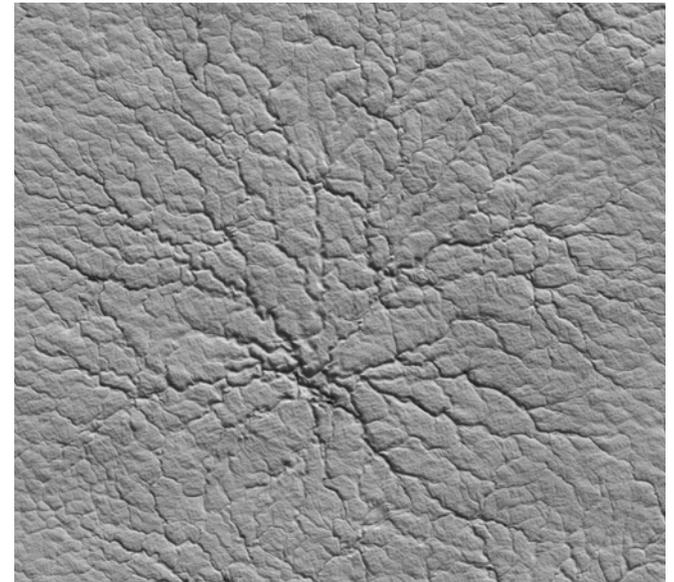

PSP_003496_0935

Ls = 226.0

PSP_003641_0935

Ls = 233.1

PSP_005579_0935

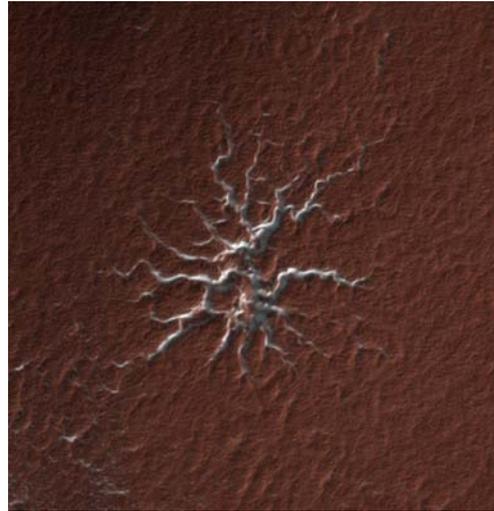

Ls = 325.4

A New Vocabulary is Required (1)

“Araneiform” (spider-like)

Isolated
araneiform
topography

*Radially organized
channels, not
connected to other
spiders*

PSP_003087_0930

Spider is 190 x 210 m

Circular
araneiform
topography

*Roughly circular
expanse, channels
do not connect to
neighboring spiders*

PSP_003443_0980

Image is ~1 km wide

Etched
araneiform
topography

*Very shallow
channels, wider
than they are
deep*

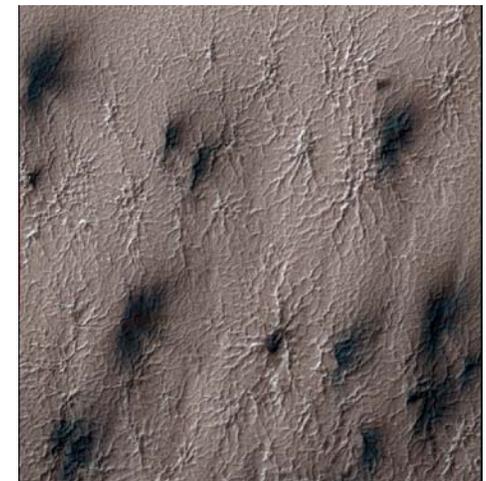

PSP_003364_0945

Image is ~1 km wide

Connected
araneiform
topography

*Radially organized
channels branch
dendritically,
connect to other
spiders' channels*

PSP_002651_0930

Image is ~1 km wide

A New Vocabulary is Required (2)

“Lace” - Dense tangle of channels, no radial organization, fewer fans

Organized
Lace

*Channels are
tortuous, some
strands are more
pronounced than
others*

PSP_002651_0930

Un-organized
Lace

*Channel
segments are
straighter, more
uniform in size*

PSP_002532_0930

Channels are ~1 m wide

“Lacertilian” (lizard-like)
Surface Texture

*Surface texture
reminiscent of
lizard skin, no deep
channels - just
grooves*

PSP_003730_0945

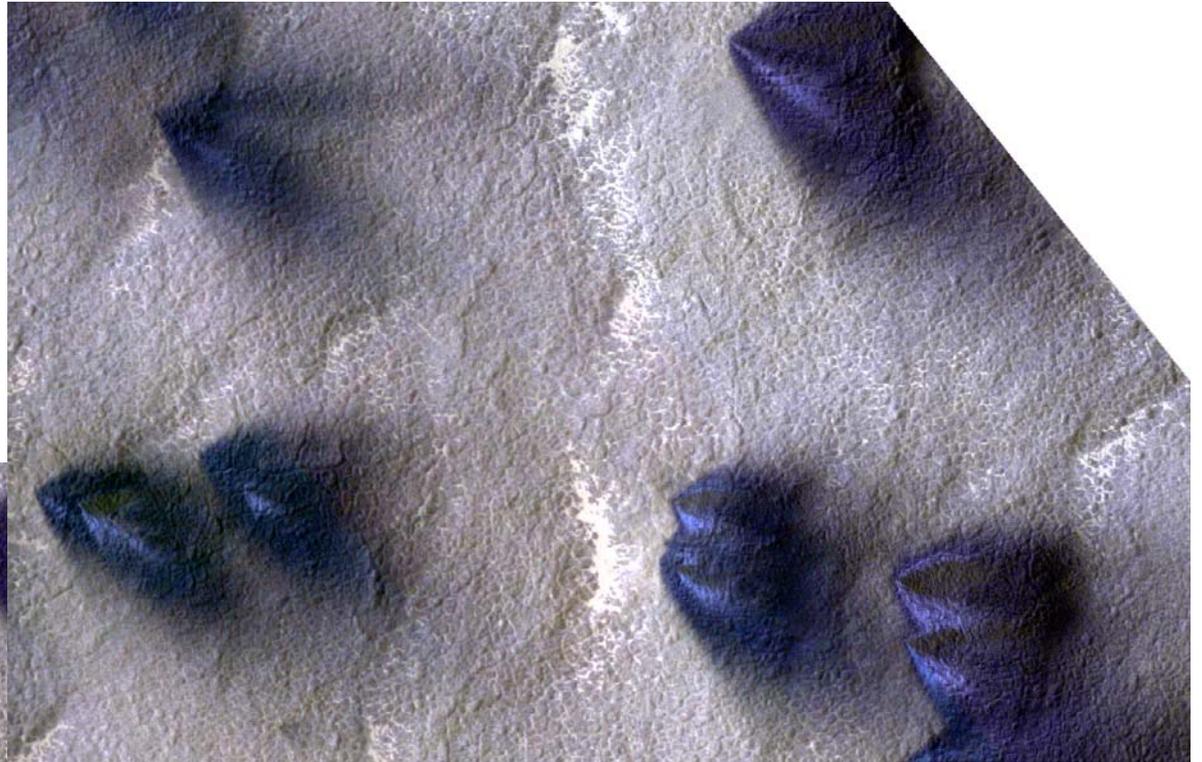

Longest fan is 140 m

Cryptic terrain
morphology may
evolve from
lacertilian to
araneiform as
channels erode and
deepen

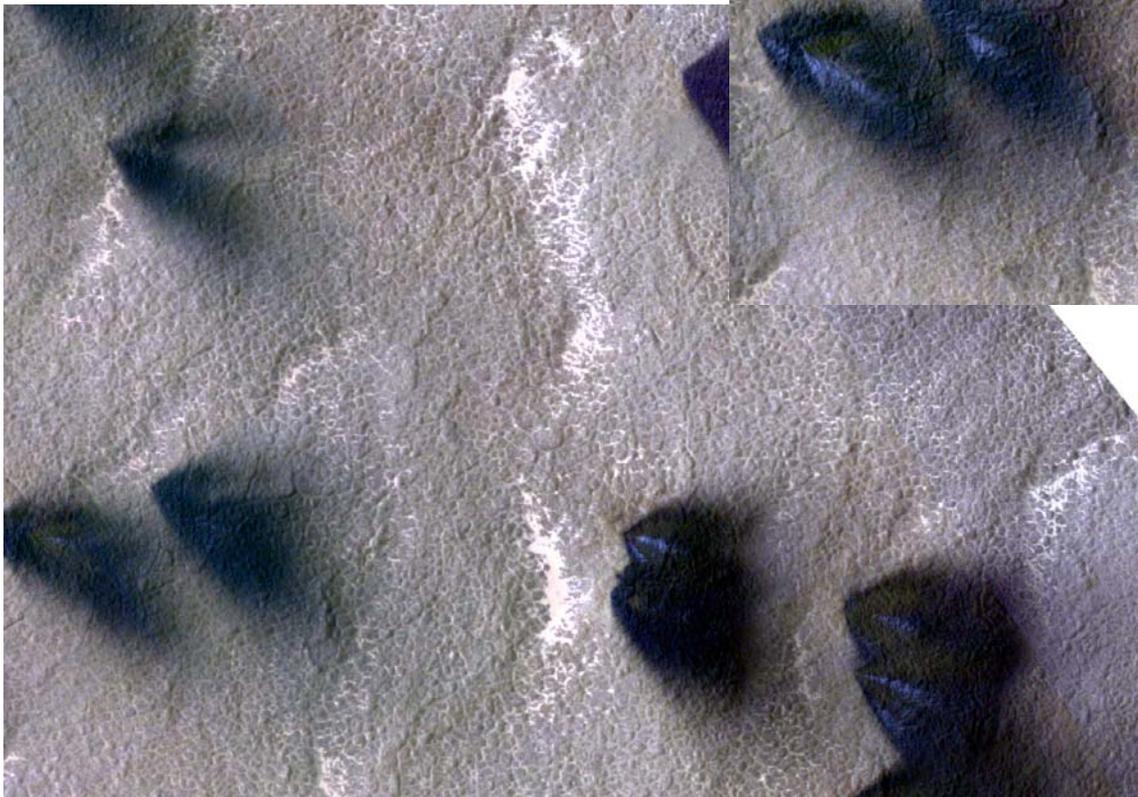

Active Processes: Bright Streaks and Dark Fans

These images were acquired
with time separation of just 106
hours

Fans show significant changes

HIRISE

PSP_002622_0945

New Findings from HiRISE

- We have just completed our campaign to image selected locations throughout spring in the southern hemisphere to watch the seasonal processes in action
 - New products: high resolution color images, anaglyphs
- Surface morphology is so un-earthly that a new taxonomy is required to describe the features we see
- Earlier hypotheses about sub-ice sublimation are substantiated by HiRISE images
- We now have data with resolution that is good enough to study the erosion of the surface by gas evaporating from dry ice - a new geological theme
- Possible now to make measurements of channels, dust volume, fans, tortuosity, etc. to derive erosion rates, study the role of underlying structure vs. solar energy
- Comparison of terrains shows how one may evolve into another as CO₂ gas erodes the surface beneath the seasonal ice
- This is just the beginning!
